This listing of claims will replace all prior versions and listings of claims in the application:

- 1 1. (Currently Amended) An apparatus for measuring speaker 2 cone displacement relative to a fixed position in an audio speaker 3 having a voice coil aligned with the <u>speaker</u> cone along an axis, 4 the apparatus comprising:
 - (a) a variable reluctance sensor device; said sensor device including a first unit fixed relative to said fixed position; and a second unit mounted for movement with affixed to said speaker cone effecting relative motion between said first unit and said second movement through motion of said speaker cone at a position on said cone radially offset from said axis;
- 11 (b) a signal injecting circuit coupled for injecting a 12 predetermined input signal into one of said first and second units; 13 and
 - (c) a signal receiving circuit coupled with said one of said first and second units for receiving a signal resulting from modulation of said input signal due to variation of reluctance of said sensor device caused by displacement of said first unit relative to said second unit, and for generating an indicating signal based upon said resulting signal; at least one signal characteristic of said indicating signal being related with said cone displacement.
 - 2. (Previously Presented) The apparatus of Claim 1, wherein said first unit comprises a core structure; and wherein said second unit comprises a electromagnetic coil structure.
 - 1 3. (Currently Amended) The apparatus of Claim 1 wherein said 2 second unit is mounted affixed to said speaker cone at a

- 3 substantially stationary node on of any modal vibration of said 4 speaker cone.
- 1 4. (Previously Presented) The apparatus of Claim 3, wherein 2 said second unit is mounted on said cone using a wedge.

5 to 6. (Cancelled)

- 7. (Previously Presented) The apparatus of Claim 1, wherein said first unit comprises an electromagnetic coil structure; and wherein said second unit comprises a core structure.
 - 8. (Currently Amended). The An apparatus of Claim 7, for measuring speaker cone displacement relative to a fixed position in an audio speaker having a voice coil aligned with the speaker cone along an axis, the apparatus comprising:
 - (a) a variable reluctance sensor device; said sensor device including a magnetic coil structure fixed relative to said fixed position; and a core structure affixed to said speaker cone effecting relative motion between said first unit and said second movement through motion of said speaker cone at a position on said cone radially offset from said axis; wherein said first unit comprising said electromagnetic coil structure operates as at least part of a high pass filter having a corner frequency; and
 - (b) a signal injecting circuit coupled for injecting a predetermined input signal into one of said first and second units; said predetermined input signal has a frequency substantially below said corner frequency; and
- 17 <u>(c) a signal receiving circuit coupled with said one of said</u>
 18 <u>first and second units for receiving a signal resulting from</u>
 19 <u>modulation of said input signal due to variation of reluctance of</u>
 20 said sensor device caused by displacement of said first unit

- 21 <u>relative to said second unit, and for generating an indicating</u>
- 22 signal based upon said resulting signal; at least one signal
- 23 <u>characteristic of said indicating signal being related with said</u>
- 24 cone displacement.

9 to 20. (Cancelled)

- 1 21. (Currently Amended) The An apparatus of Claim 2, for
 2 measuring speaker cone displacement relative to a fixed position in
 3 an audio speaker having a voice coil aligned with the speaker cone
 4 along an axis, the apparatus comprising:
 - (a) a variable reluctance sensor device; said sensor device including a core structure fixed relative to said fixed position; and a magnetic coil structure affixed to said speaker cone effecting relative motion between said first unit and said second movement through motion of said speaker cone at a position on said cone radially offset from said axis; wherein said second unit comprising said electromagnetic coil structure operates as at least part of a high pass filter having a corner frequency; and
 - (b) a signal injecting circuit coupled for injecting a predetermined input signal into one of said first and second units; said predetermined input signal has a frequency substantially below said corner frequency; and
 - (c) a signal receiving circuit coupled with said one of said first and second units for receiving a signal resulting from modulation of said input signal due to variation of reluctance of said sensor device caused by displacement of said first unit relative to said second unit, and for generating an indicating signal based upon said resulting signal; at least one signal characteristic of said indicating signal being related with said cone displacement.
